Abstract: In this paper, beamforming and precoding is combined to improve the performance of TD-SCDMA downlink based on MIMO (Multiple-Input-Multiple-Output). We deduced beamforming vector and precoding matrix combined beamforming and precoding. And then, we compared beamforming scheme based signal-to-interference-plus-noise ratio (SINR) and based signal-to-leakage-plus-noise ratio (SLNR) in TD-SCDMA Downlink System. The performance of scheme with precoding based on SINR and SLNR outperform than the scheme without precoding. As the user number or the number of receive antenna increase, the beamforming scheme with precoding outperform the traditional beamforming still, and the beamforming precoding based on SLNR is superior gradually to the beamforming precoding based on SINR.

1. Introduction
In multi-user downlink communications, a base station communicates with several co-channel users in the same frequency and time slots. It is therefore necessary to rely on transmission schemes that are able to suppress inter symbol interference (ISI) and multiple access interference (MAI). In TD-SCDMA, it is combined smart antenna at BS with joint detection technology at MS to eliminate those interferences, but the mobile terminal (MT) is expensive inevitably for its high computation and implement complex. Precoding scheme [2-5] was proposed, which can observably reduce the computation and the complexity of mobile station, especially in TD-SCDMA downlink based MIMO[3].

Beamforming forms a signal that the best combined or distributed the base band signal under the system of performance indicator [1,6], thereby, raising carrier to interference ratio of the expectations of users and avoid interference to other users. However, the antenna arrays maintain light load, the optimal array collapses the signal from the interference direction. In limited circumstances, with the number of interference users has become much, arrays continue to beamforming for expected users, but the ability of the antenna array collapse the interference signal sharp decline. With the array overload, power of all interference signals out from array has been greatly increased. On the other hand, complexity and the number of antenna restrictions, making the width of the main beam often be 10 degrees or even greater, In such a coverage of the main beam, there are often multiple users, and lead to multi-user interference. Recently, we have found that joint beamforming and precoding technologies can not only overcome the above problems, but also can improve the reliability and channel capacity.

The paper is structured as follows. The multi-user MIMO downlink system model is introduced in section 2. Section 3 derives beamforming weighted vector based on SINR and SLNR algorithms. Precoded matrix based on combination of beamforming and precoding is deduced in section 4. Simulations the performance of this scheme in the TD-SCDMA downlink based on MIMO is given in Section 5.

2. System Model
An array of \(K_a\) transmit antenna elements on BS is considered, and at each MT \(\mu_k, k = 1, \ldots, K\), an array of \(K_a\) receive antenna elements are arranged, where \(K\) is the number of MTs (i.e. users). Figure 1 shows the multi-user MIMO downlink model.

![Figure 1. The multi-user MIMO downlink model](image)

It is assumed that \(N\) data symbols have to be transmitted from BS to each MS \(\mu_k, K\) data vectors for all the MS are put together to form the total data vector[4]:

\[
d(k) = (d(k), \ldots, d(k))^T, k = 1, \ldots, K
\]

(1)

Total data vector have to be transmitted to \(K\) MT

\[
d = (d(1)^T \ldots d(K)^T)^T = (d_1 \ldots d_N)^T
\]

(2)

The data vector \(d\) of length \(KN\) is linearly modulated and mapped into a \(K_B S \times 1\) spatial spread signal \(t\).

\[
t = (t(1)^T \ldots t(K_B)^T)^T = (t_1 \ldots t_{K_B S})^T = Md
\]

(3)

\(S = NS_0, S_0\) is termed spread factor, and \(M\) is \(K_B S \times KN\) modulation matrix. The \(S \times 1\) spatial signal \(t(k_a)^T\) is transmitted by the \(k_a\) transmit antenna.

The frequency selective channel impulse responses between \(k_a\) transmit antennas at the BS and \(k_M\) receive antennas of \(K\) MTs \(\mu_k\).

\[
h(k_a, k_M) = (h^{(k_a, k_M)}(1) \ldots h^{(k_a, k_M)}(N))^T
\]

(4)

Therefore we can obtain a channel convolution matrix by \((S + W - 1) \times S\)

\[
H(k_a, k_M) = (H^{(k_a, k_M)}(1) \ldots H^{(k_a, k_M)}(N))^T
\]

(5)

\(i = 1, \ldots, S + W - 1, j = 1, \ldots, S\)
\[ H^{(k,k_b,k_{rk})}_{ij} = \begin{cases} h^{(k,k_b,k_{rk})}_{i-j+1} & , 1 \leq i-j+1 \leq W \\ 0 & , \text{else} \end{cases} \]  
$k = 1, \ldots, K; \quad k_b = 1, \ldots, K_B; \quad k_{rk} = 1, \ldots, K_M$

Then, in the case of absence of disturbing noise at the receiver inputs, the $K$ user received signals $r^{(k)}$ ($k = 1, \ldots, K$) weighted by beamforming vector of each user are to form the total received signal of dimension $KK_M(S + W - 1) \times 1$

\[ r = (r^{(1)^T} \ldots r^{(K)^T})^T = HWt_0 \]  

(7)

We assume no noise at the receiver inputs, at each MT $\mu_k$, the corresponding received signal $r^{(k)}$ is demodulated with the goal to obtain the corresponding data vector $d^{(k)}$. In the case of a linear demodulator the demodulation process at MT $\mu_k$ can be described by a demodulator matrix $D^{(k)}$

\[ d^{(k)} = D^{(k)}r^{(k)}, k = 1, \ldots, K \]  

(8)

The data vector $d^{(k)}$ of (1) intended for MT $\mu_k$ is detected without ISI and MAI.

We assume $D^{(k)} = C^{(k)} \mu_k$, $C^{(k)}$ is termed spread code matrix, which is composed of user $\mu_k$ CDMA spread code $c^{(k)} = (c^{(k)}_1 \ldots c^{(k)}_{K_B})^T$

\[ C^{(k)} = [c^{(k,k_B)} \ldots c^{(k,K_M)}]^T \]  

(9)

Here, $c^{(k,k_B)}$ is correspond to the sub spread code matrix of $\mu_k$ $k_B$ ($k_B = 1, \ldots, K_M$) receive antenna and is equal with each other. The total spread code matrices of $K$ user is $C = \text{blockdiag}(C^{(1)}, \ldots, C^{(K)})$

So we obtain the total demodulator matrices

\[ D = C^H, \quad D = \text{blockdiag}(D^{(1)}, \ldots, D^{(K)}) \]  

(11)

With (12) we can stack the $K$ equations of (8) and obtain under consideration of (7) the single equation

\[ d = Dr = DHt \]  

(13)

If we assume $B = DH$, we will obtain the data vector

\[ d = Bh = C^HHWMd \]  

(14)

Taking noise into account, the received signal $r$ will be disturbed by additive noise $n$ of dimension $KK_M(S + W - 1) \times 1$

\[ n = (n_1 \ldots n_{KK_M(S+W-1)})^T \]  

(15)

After demodulation, we can obtain the estimated data

\[ \hat{d} = D[r + n] = D[HWMd + n] = d + Dn \]  

(16)

If the dimension $K_M$ of $d$ is chosen larger than the dimension $KN$ of $a$ and if $h$ has maximum rank, i.e. if rank $B = KN < K_M$ holds, then transmit signal $t$ will exist a lot of solutions.

3. Beamforming Vector

The beamforming technique for MIMO systems simultaneously obtains downlink multi-user diversity gain and array gain. In this paper, we discuss two eigen beamforming techniques based on SINR and SLNR respectively.

3.1 Beamforming vector based SINR

It is assumed that each channel matrix $H_i$ is available at the base station and at the corresponding user, but is not required to be known by the other users. We add noise at the receiver inputs, we rewrite (7) as

\[ r_i = H_i w_i t_i + \sum_{j \neq i} H_i w_j t_j + n \]  

(17)

where the second term is the CCI caused by the multi-user nature of the system.

The signal-to-interference-plus-noise ratio (SINR) at the input of the receiver is defined as [1], [6]

\[ \text{SINR}_i = \frac{|| H_i w_i ||^2}{\sum_{j \neq i} H_i^* w_j H_j^* + \sum_{j \neq i} H_j^* w_j H_j^*} \]  

(18)

Using the SINR expression as an optimization criterion

\[ w_i = \arg \max_{w_i} \frac{|| H_i w_i ||^2}{\sum_{j \neq i} H_i^* w_j H_j^* + \sum_{j \neq i} H_j^* w_j H_j^*} \]  

(19)

Thus, the beamforming vectors is given by[6]

\[ w_i \propto \text{max eigenvector}(H_i^H H) \]  

(20)

3.2 Beamforming vector based SLNR

The following is a summary of the leakage-based solution from [7], [8]. Start from (20) and note that the power of the desired signal component for user $k$ is given by $||H_k w_k||^2$. At the same time, the power of the interference that is caused by user $k$ on the signal received by some other user $i$ is given by $||H_i H_k||^2$. We thus define a quantity, called leakage for user $i$, as the total power leaked from this user to all other users

\[ \sum_{j \neq i} H_j H_k \]  

The signal-to-leakage-plus-noise ratio (SLNR) at the input of the receiver is given by[7]

\[ \text{SLNR}_i = \frac{|| H_i w_i ||^2}{\sum_{j \neq i} H_i^* w_j H_j^* + \sum_{j \neq i} H_j^* w_j H_j^*} \]  

(21)

Using this concept of leakage, we have formulated in [8] the following decoupled optimization problem:

\[ w_i = \arg \max_{w_i} \frac{|| H_i w_i ||^2}{\sum_{j \neq i} H_i^* w_j H_j^* + \sum_{j \neq i} H_j^* w_j H_j^*} \]  

(22)

It was shown in [8] that the solution is given by

\[ w_i \propto \text{max eigenvector}(H_i^H H + \sum_{j \neq i} H_j H_j^*) \]  

(23)

where

\[ H_i = \begin{bmatrix} H_i^H \ldots H_i^H \ldots \ldots H_i^H \end{bmatrix} \]  

(24)

is an extended channel matrix that excludes $H_i$ only.

4. Precoding Combined Beamforming

We start from the received signal (7) and combine $H_i$ and $w_i$ into $\tilde{H}$ for computation simplicity as follow:

\[ r = HWt_0 + n \]

\[ = \sum_{k=1}^{K} H_i^H W^{(k)} \hat{t}^{(k)} + n \]

\[ = \sum_{k=1}^{K} \sum_{k_b=1}^{K_B} H_i^{(k,k_b)} W_{i}^{(k,k_b)} \hat{t}^{(k)} + \sum_{k=1}^{K} \sum_{k_b=1}^{K_B} \sum_{k_{rk}=1}^{K_M} H_i^{(k,k_b,k_{rk})} \hat{t}^{(k)} + n \]

\[ = \tilde{H}t + n \]  

(25)

(26)

Thus, we can get the precoding matrices used $\tilde{H}$ and $D$ which have been known at transmitter.

\[ M = f(D, \tilde{H}) \]  

(27)

For simplicity, we construct precoding matrix based zero-forcing criterion and power constraint. To consider the gain $\beta$ of the transmit filter we have to modify MSE[3]:
The first constraint is the zero-forcing criterion to suppress interference and the second constraint defined the transmit power $E_t$.

Thus, the solution of the optimize equation (28) is TxZF precoding matrix

$$M_{ZF} = \beta (D_d^H H_M D_H H_d)^{-1}$$

where

$$\beta = \frac{E_t}{\text{tr}(D_d^H H_M D_H H_d R) I}.$$  

5. Simulation

This paper simulates the schemes in TD-SCDMA based on MIMO system. According to 3GPP protocol, it is simulated with chip rate 1.28Mchip/s, and spreading factor $S_0=16$. Channel model employ parameters of multiple path fading case 3 of TD-SCDMA in 3GPP, velocity 120km/h , relative time delay[0 781 1563 2344]ns, average power [0 -3 -6 -9]dB, the length of channel impulse response $W=4$, BS use maximum likelihood to estimate channel impulse response and as channel matrix transmitted in downlink.

Figure 2 shows the BER result of beamforming precoding based on SINR (the SINR-based scheme) and beamforming precoding based on SLNR (the SLNR-based scheme) assuming $K_d=4$ transmit antenna and $K=4$ user, each user has different receive antenna. When the receiver configured by single antenna, beamforming precoding based on SINR and SLNR have no significant differences, they are superior to the traditional beamforming method by 3.5 dB gain at BER=$10^{-2}$. When the receiver configured by multiple antennas, and the number of users is $K=4$, the SINR-based scheme is better than traditional beamforming method by 2-2.6dB gain at BER=$10^{-2}$-$10^{-3}$, and the SLNR-based scheme is better than traditional beamforming method in the low SNR and worse than traditional beamforming method in the high SNR, and even worse than the receiver with single antenna beamforming precoding method with SNR increase.

Figure 3 shows the BER result of the SINR-based scheme and the SLNR-based scheme assuming $K_d=8$ transmit antenna and different user number, each user has $K_d=4$ receive antenna. With the increase of the user number, the performance of the SLNR-based scheme is superior gradually to the SINR-based scheme, but has no significant advantage.

Figure 4 shows the BER result of the SINR-based scheme and the SLNR-based scheme assuming $K_d=4$ transmit antenna and different user number, each user has different receive antenna. With the increase of the number of receive antennas, the performance of the SLNR-based scheme is better than the scheme based on SINR about 1.5 dB gain at BER=$10^{-3}$-$10^{-4}$.
